# **Exploratory Analysis with R**

Alex Sanchez, Miriam Mota, Ricardo Gonzalo and Santiago Perez-Hoyos

Statistics and Bioinformatics Unit, Vall d'Hebron Institut de Recerca

# **Outline: Exploratory Analysis with R**

- Descriptive Statistics
  - Numerical summaries
  - Graphical exploration

<sup>\*</sup>Based on this Course:\* [BIMS 8382, University of Virginia School of Medicine (USA)] (https://bioconnector.github.io/workshops/index.html).

# What packages we will use today?

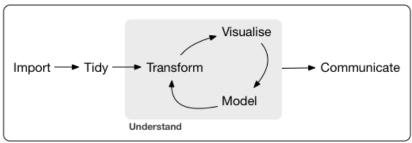

Please be sure you have the following packages installed:

- dplyr subletting, sorting, transforming variables, grouping
- ggplot2 system for creating graphics
- readxl reading .xls files

```
# install.packages("dplyr", dependencies = TRUE)
# install.packages("ggplot2", dependencies = TRUE)
# install.packages("readxl", dependencies = TRUE)

library(dplyr)
library(ggplot2)
library(readxl)
```

# The Data Science Approach in R

Program

### Section 1

# **Getting started**

# **Getting started (I)**

Load the dataset diabetes:

```
diab <- read_excel("datasets/diabetes_mod.xls")</pre>
```

② Check if we have loaded it correctly:

```
A tibble: 4 x 8
    numpacie mort tempsviu edat
                                   bmi edatdiag tabac
                                                            sbp

```

diab[1:4, 1:8]

# **Getting started (II): functions to check a dataframe:**

- Content
  - head(): shows the first few rows
  - tail(): shows the last few rows
- Size
  - dim(): returns the number of rows and the number of columns
  - nrow(): returns the number of rows
  - ncol(): returns the number of columns
- Summary
  - colnames() or names(): returns the column names
  - glimpse(): returns a glimpse of your data: structure, class, length and content of each column

# **Getting started (III)**

```

# Variables and data types

- Data managed in R is stored as variables
- Variables can be of distinct types:
  - Numerical
    - numeric (13.7)
    - int (3)
  - Character
    - "R is cute"
  - Factors
    - A,B,C,D
    - WT, Mut
  - Logical
    - TRUE/FALSE

#### Exercise I

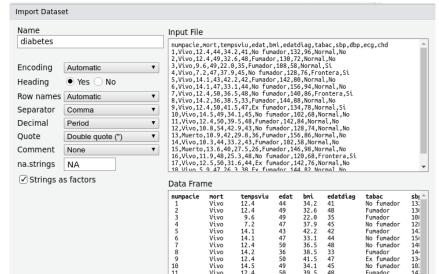

- Load the osteoporosis dataset
- Proceed similarly as to what we have done above and obtain information on
  - How many variables and observations
  - How are them (What are their types)

#### More about factors

- Each data type is what it seems to be, but factors require more explanation.
- Factors are intended to describe categories such as "sex", "blood group", but also "risk" or "stage".
- Factors are useful to describe groups without having to use numeric codes.
- Factors may be created while reading the file or later using the factor and as.factor commands.

# Create factor while reading

 Import the diabetes dataset from the diabetes.csv file using the Rstudio dialog.

# Check variable type

```
diabetes <- read.csv("datasets/diabetes.csv", stringsAsFactors=TRUE)
class(diabetes$mort)

## [1] "factor"
sapply(diabetes, class)</pre>
```

```
## numpacie mort tempsviu edat bmi edatdiag tabac
## "integer" "factor" "numeric" "integer" "numeric" "integer" "factor" "i
## dbp ecg chd
## "integer" "factor" "factor"
```

#### Repeat

 Re-read the file from excel or without setting the "stringsAsFactors" to TRUE

# **Creating factors directly**

Use factor or as factor.

```
diabetes <- read.csv("datasets/diabetes.csv", stringsAsFactors=FALSE)</pre>
class(diabetes$mort)
## [1] "character"
diabetes$mort <- as.factor(diabetes$mort)</pre>
class(diabetes$mort)
## [1] "factor"
levels(diabetes$mort)
## [1] "Muerto" "Vivo"
Warning! by default alphabetic order is used when creating factor levels.
vitalStatus <- factor(diabetes$mort, levels=c("Vivo", "Muerto"))</pre>
class(vitalStatus)
## [1] "factor"
levels(vitalStatus)
```

# Change the levels of a factor

- When humans fill the database... many errors can happen :(
  - An answer like "YES", could be entered like:

```
"YES", "yes", "Yes", "Yeah "
```

- All this possible answers will become differents levels for the same factor variable
- This may be solved using recode\_factor:

```
diab$mort <- recode_factor(diab$mort, "Muerto" = "muerto")
levels(diab$mort)</pre>
```

```
## [1] "muerto" "Vivo"
```

# Changing characters (chr) to factors (Factor)

An alternative way to turn characters into factors is the mutate\_if function:

```
glimpse(diab)
## Rows 149

## **Grouped summeries**

If we want to group the descriptive summaries by other variables we can use group\_by function:

```
diab %>%
 group by(tabac, ecg) %>%
 summarize(mean(edat))
## `summarise()` has grouped output by 'tabac'. You can override using the `.groups` argument.
  # A tibble: 9 x 3
## # Groups:
               tabac [3]
     tabac
                ecg
                         `mean(edat)`
     <fct>
                <fct>
                                <db1>
## 1 Ex fumador Anormal
                                 68.5
## 2 Ex fumador Frontera
                                 59.8
## 3 Ex fumador Normal
                                 51.1
                                 58
## 4 Fumador
               Anormal
             Frontera
                                 44.8
## 5 Fumador
                Normal

## 9 No fumador Normal

# Handling missing data

- What happens if we have missing data in our dataset?
- The file diabetes\_mod.xls contains some missings

```
diabetes_mod <- read_excel("datasets/diabetes_mod.xls")
diab <- diabetes_mod %>% mutate_if(is.character, as.factor)
mean(diab$sbp)
```

## [1] NA

#### **NA** indicates *missing data* in the variable

#### Let's look the sbp variable:

```
diab$sbp
```

```
## [1] 132 130 108 128 142 156 140 144 134 102 142 128 156 102 146 120 142 144 ## [19] NA 134 130 122 132 150 134 142 124 102 134 118 192 122 122 112 142 152 ## [37] 112 118 152 136 134 130 108 126 132 144 126 128 NA 128 142 132 148 170 ## [55] 140 138 112 140 138 130 178 158 168 146 128 132 154 154 122 144 178 162 ## [73] 142 120 124 174 142 160 122 162 132 116 152 144 98 138 138 184 158 176 ## [91] 118 172 182 144 142 154 122 222 150 142 128 122 162 172 132 112 138 128 ## [109] 132 120 140 140 172 136 152 126 104 142 128 122 122 122 122 122 168 162 NA ## [127] 126 180 132 150 106 154 122 120 120 144 134 148 170 160 154 124 130 156 ## [15] 162 132 120 160 146

# **Numerical Summaries (VIII)**

How to work with *missing data*:

```
sum(is.na(diab$sbp))
## [1] 3
sum(is.na(diab$dbp))
## [1] O
diab_noNAS <-na.omit(diab)</pre>
dim(diab)
## [1] 149 11
dim(diab_noNAS)
```

See also: Remove Rows with NA in R Data Frame

## [1] 141 11

#### **EXERCISE**

- With the diab dataset
- Show only the rows from 35 to 98 and columns 5, 7, and from 9 to 11
- Change the level of the variable tabac, from No Fumador to No\_Fumador
- Display the unique values for the variable bmi. Count how many exist.
- Display the mean of edatdiag, grouped by ecg

#### Section 3

# Exploratory Data Analysis (EDA): Graphical summaries

# Exploratory Data Analysis (EDA): Graphical summaries

- We could dedicate one whole course to Data Visualization (at least see our "Statistical Pill on Data Visualization")
- Here we will only see the most common approaches to visualize data:
  - Histograms
  - Barplots
  - Piecharts
  - Boxplots
  - Scatterplots

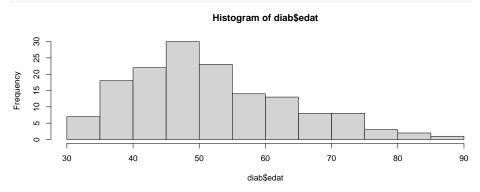

# R graphics engines

- R is very powerful and flexible at doing graphics.
- This comes at a price: Complex graphics (that we do not show here) may require sonme extra effort.
- Much work has been done to simplify this
  - There exist graphical tools that allow for the interactive construction of plots.
  - There exist new approaches to plotting that try to be more intuitive than "traditional" ones.
- ggplot is one of such approaches.

## **Histograms**

- We will use histograms to plot the frequencies of each range of values in continuous variables.
- These plots provide an approximation to the distribution of the variables being represented.

#### hist(diab\$edat)

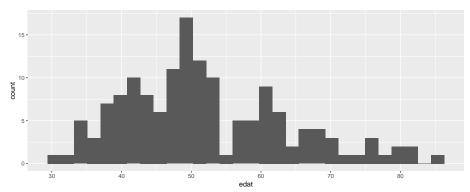

# A histogram in ggplot

- Every ggplot has, at least, three components
  - The data used
  - The variables that go in each axis (the "aesthetics")
  - The type of plot
- Plots are built progressively "adding layers"

```
library(ggplot2)
ggplot(data=diab, aes(x=edat))+
  geom_histogram()
```

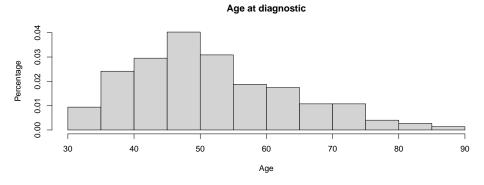

## `stat\_bin()` using `bins = 30`. Pick better value with `binwidth`.

# Improving plots with graphic parameters

- Plots can be improved using graphical parameters
- Some parameters are the same in all graphs. Others are specific of one or other graph.

hist(diab\$edat, main="Age at diagnostic", probability = TRUE, xlab="Age", y

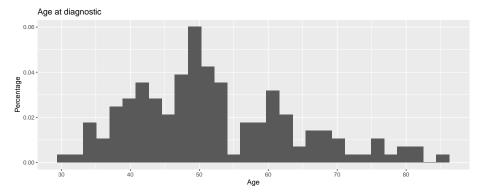

# Improving plots in ggplots

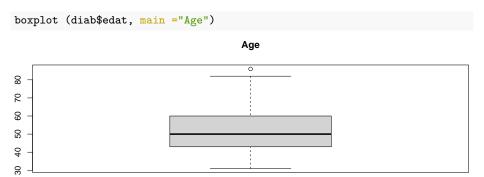

- Plots can be improved using graphical parameters
- Some parameters are the same in all graphs. Others are specific of one or other graph.

```
ggplot(data=diab, aes(x=edat))+
geom_histogram(aes(y=..density..))+
ggtitle("Age at diagnostic")+
xlab("Age") + ylab("Percentage")
```

## `stat\_bin()` using `bins = 30`. Pick better value with `binwidth`.

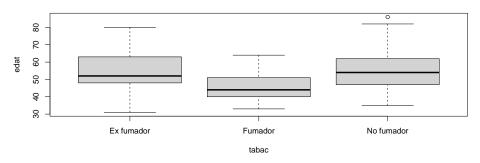

# Boxplot. A one-dimensional histogram

# **Boxplot: Decomposing plots by groups**

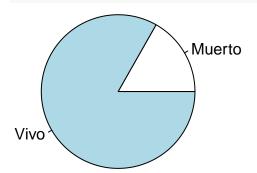

#### Age at diagnostic according smoking status

# Plots for categorical variables

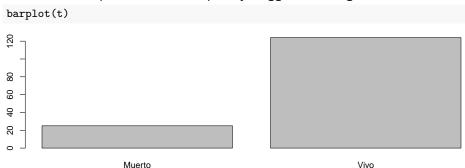

- Some simple principles
  - Use pie charts only with categorical variables in nominal scale
  - Use barplots for any categorical variable
  - Never use 3D-plots

```
t <- table(diab$mort)
pie(t)</pre>
```

## **Barplots**

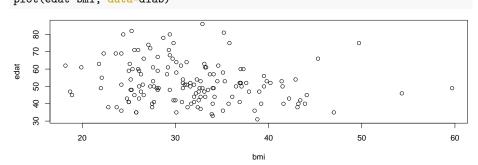

• Similar to pie charts but, implicitly, suggest ordering

# **Scatterplots**

• For two variables, simply use plot

plot(edat~bmi, data=diab)

#### **EXERCISE**

- With the diab dataset.
  - Use the best graphic type to plot the relation between sbp and dbp
  - Show graphically the relation between edat and ecg
  - Plot the *sbp* frequencies

#### **EXERCISE**

- Using the osteoporosis.csv dataset
- Load the dataset and check if it is correctly loaded
- Calculate the mean and standard deviation of imc grouped by clasific
- Plot the distribution of edat
